Class Binding in Angular

1 Comment / 3 minutes of reading

← Style Binding Component Style →

The Angular Class binding is used to add or remove classes to and from the HTML elements. You can add CSS Classes conditionally to an element, hence creating a dynamically styled element.

The Angular provides the three ways to add/remove classes to and from the element. One using the DOM `ClassName` Property. The second option is to use the `Class` shorthand. The third option is to use the NgClass directive, which is covered in a separate tutorial.

Applies to: Angular 2 to the latest edition of i.e. Angular 8, Angular 9, Angular 10, Angular 11

- Conditionally binding class

Class binding with NgClass
Summary

Class binding with ClassName

The `ClassName` is the property name of HTML Element. Hence we can make use of Property binding to assign the class name to any HTML element.

The following example assigns CSS Class red to the div element.

```
<div [className]="'red'">Test</div>
```

You can also add more than one class by separating them using the

```
<div [className]="'red size20'">Test</div>
```

HTML Class attribute

You can also add class using the normal HTML way.

```
<div class="red">red</div>
```

and, mixing both `class` and `[className]` results in removal of `class` attribute. You cannot use both.

```
<div class="red" [className]="'size20'">red</div>
```

Conditionally apply Classes

We can also bind the class name dynamically.

To do that first create a variable in your component class.

```
cssStringVar: string= 'red size20';
```

And then use it in the Template as shown below.

```
<div [className]="cssStringVar">Test</div>
```

You can create a function, which returns the class based on some condition.

```
getClass() {
  return 'red';
}
```

and then use it in the template as shown below.

```
<div [className]="getClass()">getClass</div>
```

The following example uses the Conditional (Ternary) Operator.

```
<div [className]="hasError() ? 'red' : 'size20'"> conditonal operator </div>
```

Class binding with Class

There are another shorthand way to bind CSS Class to HTML element.

```
<div [class.<className>]="condition"></div>
```

Where

className is name of the class, which you want to bind to.

condition must return true or false. A return value of true adds the class and a false removes the class.

In the following example, the class `red` and `size20` is added to the `div` element.

```
<div [class.red]="true" [class.size20]="true">Test</div>
```

Conditionally binding class

To dynamically or conditionally bind a class, First create a variable in the component class as shown below.

```
hasError:false;
```

```
<div [class.red]="hasError" [class.size20]="hasError">Test</div>
```

You can also create a function `hasError()`, which should return true or false as shown below.

```
hasError() {
   return false
}
```

And use it in the template as shown below.

```
<div [class.red]="hasError()" [class.size20]="hasError()">Test</div>
```

Class binding with NgClass

Another way to add class is to use the `NgClass` directive. It is offers a more flexibility, like easily adding multiple classes etc. You can read about ngClass in Angular.

Summary

The class binding is one of the many ways in which you can style angular apps. The following is the list of all articles on styling angular application.
